Abstract

We present in this paper a study on the thermal behavior of a square micro coil that will be integrated in a DC-DC micro converter. The first, we calculate the value of inductance. The second, we described our micro coil; dimensioning, electrical model, and formula of loss. A buck micro converter schematic simulation coupled with ideal and integrated micro coil was presented. This conceptual model of the buck is best understood in terms of the relation between current and voltage of the inductor. Finally, we determined a mathematical expression giving the evolution of temperatures in an integrated micro coil using the separation of variables method and a visualization of the thermal behavior is determined in 2D and 3D space dimension using the finite element method.

Keywords: micro coil, integrated, micro converter DC-DC, temperature

1. Introduction

In Power electronics, modeling of passive components constitute a particularly important issue. Indeed, the magnetic components, inductors and transformers are mainly used to transmit or store energy. The passive elements volume reduction leads to a mounted in operating frequency, but this increase in frequency causes an increase in losses. If the behavior of some components is relatively insensitive to temperature changes, it is not the same thing for magnetic components whose characteristics depend strongly on the temperature. The losses freed in the form of heat are become a major concern due to the reduction of trade with the outside surfaces and increasing the density of losses. Under these conditions, the inclusion of temperature and its influence on the magnetic and electrical characteristics of the component is essential. In this regard, several studies were conducted, first by the development of a compact model for the determination of the integrated component temperature [1], the study of the thermal model of integrated passive component based on the method node [2], the study of the thermal behavior in a bilayer materials by the method of separation of variables [3], the study of the thermal model of an integrated circuit by the method of Green [4] and finally the determination of the operating temperature of the integrated by a thermal analytical model passive component (Cauer model) [5]. The purpose of this work is the design and manufacturing of a micro coil for a micro converter. In operation, this reel is the seat of heat loss that we must quantified to ensure proper operation. Beyond a certain temperature, this micro coil may deteriorate and affect the operation of micro inverter. This led us to tackle the problem of thermal modeling of a square spiral coil micro plane. We have implemented the literature processes for the design of our micro coil and calculation of losses that are different from the heat. We have also developed mathematical models that allowed us to determine the thermal behavior of our component. The Solving of mathematical equations by the method of separation of variables [5] and the finite element method has allowed us to see the evolution of the temperature in the different parts that make up the micro coil in 2D and 3D.

2. Presentation of the Micro Converter

We have chosen a Buck micro converter continuous-continuous step-down (Figure 1) [6-9]. The micro coil to integrate will thus be dimensioned for this type of application. Input
voltage, $V_{in} = 3\text{Volt}$. Output voltage, $V_{out} = 1.5\text{Volt}$. Maximum current $I_{L,\text{max}} = 0.65\text{A}$. Output power, $P_{out} = 0.6\text{W}$. Frequency of operation, $f = 1\text{MHz}$.

Figure 1. Buck converter

The average output current $I_{out}$ is calculated by formula (1):

$$I_{out} = \frac{P_{out}}{V_{out}}$$

(1)

$I_{out} = 0.4\text{A}$, $I_{out} = L_{L} - I_{c}$, $I_{c} = 0$, $I_{out} = I_{L}$. The peak amplitude of the current through the micro coil is calculated by formula (2):

$$\Delta I_{L} = I_{L,\text{max}} - I_{L,\text{min}}$$

(2)

The average current $I_{L}$ is expressed as follows (3):

$$I_{L} = \frac{I_{L,\text{max}} + I_{L,\text{min}}}{2}$$

(3)

Where,

$I_{L,\text{min}} = 2I_{out} - I_{L,\text{max}}$, $I_{L,\text{min}} = 0.016\text{A}$, $\Delta I_{L} = 0.96\text{A}$ and $\alpha = V_{out} / V_{in} = 0.5$.

The current which flows through the micro coil increases according to relation (4):

$$\Delta I_{L} = \frac{\alpha(1-\alpha)V_{in}}{L_{c}}$$

(4)

We can calculate the value of the inductance $L$ [9] according to relation (5):

$$L = \frac{\alpha(1-\alpha)V_{in}}{\Delta I_{L}}$$

(5)

The maximum energy stored in the micro coil is given by relation (6):

$$W = \frac{1}{2}LI_{out}^{2}$$

(6)

The volumetric energy density of the ferrite is given by the equation (7):

$$W_{v,\text{max}} = \frac{B_{\text{max}}^{2}}{2\mu_0\mu_r}$$

(7)

$B_{\text{max}}$: The maximum magnetic induction supported by the ferrite

$\mu_r$: The relative permeability
\( \mu_0 \): The magnetic permeability of the free space

The volume of the ferrite is given by relation (8):

\[
Vol = \frac{W}{W_{\text{max}}}
\]

(8)

The ferrite’s thickness is \( t_{\text{sub}} = 97 \mu \text{m} \), thus the volume will be \( 2100 \times 2100 \times 97 \mu \text{m}^3 \).

3. Dimensioning of Integrated Inductor

The geometry parameters characterizing the integrated micro coil (Figure 2) are the number of turns \( n \), the width of the conductor \( w \), thickness of the conductor \( t \), the spacing between conductor \( s \), length of the conductor \( l \), the outer diameter \( d_{\text{out}} \) and input diameter \( d_{\text{in}} \).

![Figure 2. Geometry of integrated square spiral inductor](image)

We find in the literature several formulas which allow us to calculate the number of turns \( n \) according to the value of inductance \( L \), we chose the Weeler’s [10-11] formula (9).

\[
L_{\text{new}} = K_1 \mu_0 \frac{n^2 d_{\text{avg}}}{1 + k_2 \rho}
\]

(9)

Where, we define the average diameter as \( d_{\text{avg}} = (d_{\text{out}} + d_{\text{in}}) / 2 \) [12]. \( A_m \) the factor’s form defined as \( A_m = d_{\text{out}} - d_{\text{in}} / d_{\text{out}} + d_{\text{in}} \). The coefficients \( k_1 \) and \( k_2 \) are defined for each geometry.

For a square micro coil spiral, \( k_1 = 2.34 \) and \( k_2 = 2.75 \).

The spacing between conductors is expressed as follows (10):

\[
s = \frac{d_{\text{out}} + d_{\text{in}} - 2wn}{2(n-1)}
\]

(10)

The length of the trace is expressed as follows (11)

\[
l = 4n[d_{\text{out}} - (n - 1)s - mw] - s
\]

(11)

The skin thickness is defined as (12)

\[
\delta = \sqrt{\frac{\rho}{\pi f}}
\]

(12)

Where \( \rho \) represent the resistivity of the conductor, \( \rho_{\text{copper}} = 1.7 \times 10^{-8} \Omega \cdot \text{m} \) and \( \mu \) its magnetic permeability. So that the current flows in the entire conductor, it is necessary that one of the
following conditions is filled, \( w \leq 2\delta \) or \( t \leq 2\delta \), \( \delta = 65.65\mu m \). Table 1 contains the specifications and the design results of the square spiral integrated micro coil.

4. Electrical Model

The equivalent electrical model of the integrated micro coil [13-18] is shown in Figure 3.

The series resistance \( R_s \), can be approximated as (13):

\[
R_s = \frac{\rho l}{w} \tag{13}
\]

The parasitic capacitive can be modeled as \( C_s \) (14):

\[
C_s = \frac{\varepsilon_0 l}{s} \tag{14}
\]

Where, \( \varepsilon_0 \) is the permittivity of free space, \( \varepsilon_0 = 8.85418710^{-12} Mm^{-1} \).

The substrate capacitance \( C_{\text{sub}} \) and resistance \( R_{\text{sub}} \) are approximately proportional to the area occupied by the integrated micro coil and can be expressed as (15), (16).

\[
C_{\text{sub}} = \frac{1}{2} \varepsilon_0 \varepsilon_r \frac{lw}{l_{\text{sub}}} \tag{15}
\]

\[
R_{\text{sub}} = 2 \rho_{\text{sub}} \frac{t_{\text{sub}}}{lw} \tag{16}
\]

\( C_{\text{ox}} \) oxide capacitance SiO\(_2\) can be expressed as (17):

\[
C_{\text{ox}} = lw \left( \frac{\varepsilon_0 \varepsilon_{\text{ox}}}{t_{\text{ox}}} \right) \tag{17}
\]
Where $\varepsilon_r, \rho_{sub}$ represent respectively the relative permittivity and the resistivity of substrate and $t_{ox}$ the oxide thickness. In our case, $\varepsilon_r = 10$, $\rho_{sub} = 4.5 \times 10^{-6} \Omega \cdot m$ and $t_{ox} = 10 \mu m$. The geometry of a square spiral integrated micro coil on substrate [19-20] is shown in Figure 4.

![Figure 4](image)

Figure 4. Geometry of integrated square spiral inductor on substrate, (a) 3D view, (a) 2D view

The efficiency of integrated micro coil is calculated [21-22] according by relation (18):

$$Q = 2\pi \frac{\text{stored energy}}{\text{dissipated energy}}$$

Table 2 presents electrical parameters of the integrated micro coil.

5. Loss Determination

The loss in the conductor [23-26] can be expressed as (19):

$$P_c = R_s I^2 + R_{AC} \Delta I_L^2$$

Where, $R_{AC}$ is the resistance at alternative current (20).

$$R_{AC} = \frac{\rho l}{\delta (1 - e^{-\delta/(l/\delta)})}$$

6. Simulation of the of the Micro Converter

In this simulation, the circuit of Figure 5 contains an ideal micro coil and the Figure 6 shows the waveform of the output voltage and current of the Buck micro converter. When the switch is closed, the voltage across the inductor is $V_L = V_{in} - V_{out}$. The current through the inductor
rises linearly. As the diode is reverse-biased by the voltage source, no current flows through it. When the switch is opened, the diode is forward biased. The voltage across the inductor is \( V_L = -V_{out} \). The current through inductor decreases.

Figure 5. Schematic of buck micro converter coupled with ideal micro coil

Figure 6. Waveforms of voltage and current of buck micro converter coupled with ideal micro coil

Figure 7 shows the schematic of micro converter simulated coupled with integrated micro coil. The simulated results are indicated in Figure 8. We observe the same result with ideal and reel inductor.

Figure 7. Schematic of buck micro converter coupled with integrated micro coil

Figure 8. Waveforms of voltage and current of buck micro converter coupled with integrated micro coil

The results we obtained (Figure 6, Figure 8) were compared with those from the literature [27]. We notice the same evolutions therefore quite acceptable and in very good agreement.
7. Thermal Modeling of Integrated Inductor

In this section we will predict the evolution of the temperature in an integrated square spiral micro coil using:

a) Mathematical model based of the separation of variables method [28-30].

b) Visualization of the thermal behavior based of the finite element method [31-34].

We present an integrated micro coil in the air, with thickness L and heat source q (Figure 9). We consider also an integrated square spiral micro coil on substrate. \( k_1 \), \( k_2 \) and \( k_3 \) be the thermal conductivities for the first layer in \( 0 \leq y \leq L_1 \), second in \( L_1 \leq y \leq L_2 \) and third in \( L_2 \leq y \leq L_3 \). \( q \) is the heat source. Initially, the three layers are at temperature \( T_0 \). The boundary surface at \( y=0 \) is kept at temperature \( T_0 \) and the boundary at \( y = L_1 + L_2 + L_3 \), dissipate heat by convection with \( h \) constant (Figure 10).

\[ \begin{align*}
\frac{\partial^2 T}{\partial y^2} + \frac{1}{k} q &= \frac{1}{\alpha} \frac{\partial T}{\partial t} \\
\end{align*} \]

(21)

For solve this equation, we can determinate the solution analytical for homogeneous problem \( T_h(y,t) \), and the solution of steady-state problem \( T_s(y) \). The solution for the original problem (21) is determined from:

![Figure 9. Transversal cup of an integrated micro coil in the air](image)

![Figure 10. Transversal cup of an integrated micro coil on substrate](image)

Our component consists of four domains. The domain of air surrounding our square spiral micro coil. The copper is the conductor material, the substrate is in NiFe, and the dielectric is in oxide SiO2. The thermal characteristics of materials are shown in Table 3.

7.1. Mathematical Model

The mathematical formulation of an integrated square spiral micro coil in the air is given as (21):

\[ \begin{align*}
\frac{\partial^2 T}{\partial y^2} + \frac{1}{k} q &= \frac{1}{\alpha} \frac{\partial T}{\partial t} \\
\end{align*} \]

(21)

For solve this equation, we can determinate the solution analytical for homogeneous problem \( T_h(y,t) \), and the solution of steady-state problem \( T_s(y) \). The solution for the original problem (21) is determined from:
To solve the homogeneous problem, we use the separation of variable of equation $T_h(y, t)$ into a space and time.

$$T_h(y, t) = \Gamma(t)Y(y)$$

The function $Y(y)$ become (24):

$$\frac{d^2 Y(x)}{dy^2} + \beta^2 Y(y) = 0$$

The solution for $\Gamma(t)$ is given as (25):

$$\Gamma(t) = e^{-\alpha \beta^2 t}$$

The solution for $T_h(y, t)$ is given as (26):

$$T_h(y, t) = \sum_{n=1}^{\infty} c_n e^{-\alpha \beta^2 t} \cdot Y(\beta_m, y)$$

For $t=0$, equation (26) becomes (27):

$$T_0 = \sum_{m=1}^{\infty} c_m Y(\beta_m, y)^2$$

With,

$$c_m = \frac{1}{N(\beta_m)} \int_{y=0}^{L} Y(\beta_m, y')T_0 dy'$$

$$N(\beta_m) = \int_{0}^{L} Y^2(\beta_m, y) dy$$

The analytical solution 1D for equation (21) is given as (30):

$$T_h(y, t) = \sum_{m=1}^{\infty} \frac{e^{-\beta_m^2 t}}{N(\beta_m)} \int_{y=0}^{L} Y(\beta_m, y')T_0 dy'$$

With, $Y(\beta_m, y) = \sin \beta_m y$, $\frac{1}{N(\beta_m)} = \frac{2}{L}$ and $\sin \beta_m y = 0$. $\beta_m = m \pi / a$, $m = 1, 2, 3, \ldots$

$T_i(y)$ is the solution of the steady-state.

The mathematical formulation of an integrated square spiral micro coil on substrate is given as (31), for $i=1, 2, 3$.

$$\frac{\partial^2 T_i}{\partial y^2} + \frac{q}{k_i} = \alpha_i \frac{\partial T_i}{\partial t}$$
For solve this equation, we can determinate the solution analytical for homogeneous problem \( \theta_i(y, t) \), and the solution of steady-state problem \( T_i(y) \). We use the Green's function of heat conduction problems with heat source. The solution is determined from (32).

\[
T_i(y, t) = \theta_i(y, t) + T_i(y)
\]

(32)

The temperature boundary conditions are determined from (33).

\[
\begin{align*}
\theta_i &= 0, \text{ at } y = 0 \\
\lambda_i \frac{\partial \theta_i}{\partial y} &= \lambda_{i+1} \frac{\partial \theta_{i+1}}{\partial y}, \text{ at interface, } i = 1, 2 \\
\theta_i &= \theta_{i+1} \\
\lambda_i \frac{\partial \theta_i}{\partial y} + h \theta_i, \text{ at } y = L_1 + L_2 + L_3
\end{align*}
\]

(33)

\( h \) represent the convective heat transfer coefficient. The initial condition is (34).

\[
\theta_i(y, t) = T_0
\]

(34)

Where \( \theta_i(y, t) \), is the temperature of the layer \( i \).

For obtain the analytic solution of each layer, we use the solution by separation of variables (35)

\[
\theta_i(y, t) = \Gamma_i(t) \Psi_i(y)
\]

(35)

We determinate \( \theta_i(y, t) \) with equation (36).

\[
\theta_i(y, t) = \sum e^{-\beta_i t} \left[ A_n \sin \frac{\beta_n y}{\alpha_i} + B_n \cos \frac{\beta_n y}{\alpha_i} \right] C_n
\]

(36)

The temperature distribution (36) must satisfy the initial condition (37).

\[
T_0 = \sum C_n \Psi_{in}(y)
\]

(37)

By applying the operator \( \frac{\lambda_i}{\alpha_i} \int_{y_i}^{y_{i+1}} \Psi_{ir} \) to the both sides of equation (37), we find (38).

\[
\sum_{i=1}^{M} \frac{\lambda_i}{\alpha_i} \int_{y_i}^{y_{i+1}} \Psi_{ir} \psi_{in} \, dy = \sum_{n}^{Nn} C_n \left[ \sum_{i=1}^{M} \frac{\lambda_i}{\alpha_i} \int_{y_i}^{y_{i+1}} \Psi_{ir} \Psi_{in} \, dy \right]
\]

(38)

Where, \( M \) is the number of layer (\( M = 3 \)).

\[
\sum_{i=1}^{M} \frac{\lambda_i}{\alpha_i} \int_{y_i}^{y_{i+1}} \Psi_{ir} \psi_{in} \, dy = \begin{cases} 0 & n \neq r \\ N_n & n = r \end{cases}
\]

(39)

The \( N_n \) and \( C_n \) expressions are defined, respectively, as follows (40), (41).
Finally, the temperature expression is now (42).

\[
\theta_i(y, t) = \sum_{n=1}^{\infty} \frac{1}{N_n} \sum_{j=1}^{N_n} \int_{y_{j-1}}^{y_j} \Psi_{j_n} \left( y \right) T_0 \, dy
\]

We replace \( \Psi_{j_n} \) by its expression, we will have (43).

\[
\theta_i(y, t) = \sum_{n=1}^{\infty} \frac{1}{N_n} e^{-\beta_n z^2} \frac{\beta_n y}{\sqrt{\alpha_i}} (A_{in} \sin \frac{\beta_n y}{\sqrt{\alpha_i}} + B_{in} \cos \frac{\beta_n y}{\sqrt{\alpha_i}}) G
\]

The solution \( T_j(y) \) is determined from (44).

\[
T_j(y) = \phi_j(y) T_0 + \Psi_j(y) T_0
\]

The functions \( \phi_j(y) \) and \( \Psi_j(y) \) are the solutions of the steady-state. The solution of the heat equation with heat source is given by Green’s function \( G_{ij}(y, t | y', t') \) [35-41](45).

\[
T_j(y, t) = \sum_{j=1}^{M} \left\{ \int_{y_j}^{y_{j+1}} G_{j'}(y, t | y', t') \left[ \int_{y'_j}^{y_{j+1}} q_{j'} \, dy' \right] \right\} T_0 \, dy' + \int_{t=0}^{t} \, dt
\]

7.2. Results

In this section, we present the temperature profile of our integrated micro coil. These results relate the variation and temperature distribution in each layer, conductor, dielectric and substrate. Figure 11 shows the temperature profile in an integrated micro coil on the air.

![Figure 11. Temperature profile in an integrated inductor on the air](image)

In Figure 12(a), (b) and (c), we observe the evolution of temperature in an integrated micro coil on substrate in a conductor, dielectric and in a substrate, respectively. The
temperature distribution increase in the copper and it decreases in the silicon oxide layers, and the substrate. Our results were compared with those from the literature [5]. We notice the same evolutions therefore quite acceptable and in very good agreement.

![Graph showing temperature distribution](image)

### 7.3. Visualization of the Thermal Behavior

In this section, we present the temperature distribution in our integrated micro coil, based on the finite element method [42].

Geometry of this study is created in 2D and 3D space dimension. This distribution is obtained by solving the equation (46) of heat taking into account certain boundary conditions.

\[
\rho C_p \frac{\partial T}{\partial t} - \nabla (k \nabla T) = q
\]

In Figure 20, we observe the temperature distribution in the micro coil on substrate, (a) on isosurface, (b) on the upper surface, (c) on surface, (d) on scile, (e) on contour. We see from these figures that the temperature attained is from 37 °C. Our results were compared with those from the literature [5]. We notice the same evolutions therefore quite acceptable and in very good agreement.

In Figure 21, we observe the total heat flux distribution in the micro coil on substrate.

8. Conclusion

Thermal modeling of an integrated square spiral micro coil is a very important point in microelectronic system. In this study, the temperature distribution in the different layers of integrated micro coil can be determined as a function of position and time from the heat conduction equation using two methods. The first is a mathematical model based of the separation of variables. The second nomad element finite is presented for a good visualization of thermal behavior in our component. Our geometry is created in 2D and 3D space dimension. It is found that the temperature in micro coil increase considerably when we add substrate. It has been demonstrated that the dependences of the heat source and loss, can be simulated the thermal behavior.
